    Most benchmarks are built using one or more types of
    profile-driven feedback.  The types used are designated
    by abbreviations in the notes:

    +CFB: Code generation is optimized by the compiler, using
          feedback from a training run.  These commands are
          done before the first compile (in phase "fdo_pre0"):

                mkdir /tmp/pp
                rm -f /tmp/pp/${baseexe}*

          and these flags are added to the first and second compiles:

                PASS1_CFLAGS = -prof_gen_noopt -prof_dir /tmp/pp
                PASS2_CFLAGS = -prof_use       -prof_dir /tmp/pp

         (Peak builds use /tmp/pp above; base builds use /tmp/pb.)

    +IFB: Icache usage is improved by the post-link-time optimizer
          Spike, using feedback from a training run.  These commands
          are used (in phase "fdo_postN"):

                mv ${baseexe} oldexe
                spike oldexe -feedback oldexe -o ${baseexe}

    +PFB: Prefetches are improved by the post-link-time optimizer
```

Notes/Tuning Information (Continued)

```
        Spike, using feedback from a training run.  These
        commands are used (in phase "fdo_post_makeN"):

             rm -f *Counts*
             mv ${baseexe} oldexe
             pixie -stats dstride oldexe 1>pixie.out 2>pixie.err
             mv oldexe.pixie ${baseexe}

        A training run is carried out (in phase "fdo_runN"), and
        then this command (in phase "fdo_postN"):

             spike oldexe -fb oldexe -stride_prefetch -o ${baseexe}

    When Spike is used for both Icache and Prefetch improvements,
    only one spike command is actually issued, with the Icache
    options followed by the Prefetch options.
